The appts. for the mixture of anticoagulants with fresh blood has a horizontal holding dish (1) for the blood bag which is rotated by two vertical journals (3,4), at a given distance from each other. The two journals (3,4), with the same eccentricity, are fitted to an eccentric disc (9,10) rotating round vertical axes (7,8). At least one eccentric disc (9,10) is rotated by a drive (2). Also claimed is an operation where the blood bag with the liquid anti-coagulant and the inflowing fresh blood is held horizontally and given a horizontal tumble movement in a circular pattern.

ADVANTAGE - The system ensures an even and thorough mixing of the anticoagulant with the fresh blood, while blood is being taken.
